Automatic Stripe Analysis Tool

Justin R. Bickford
Sensors and Electron Devices Directorate, ARL
This report discusses the design and implementation of an automatic stripe analysis application for use in metrology. It has been implemented in Mathworks’ Matlab scripting environment and wrapped in an easy-to-use graphical user interface (GUI). The algorithm is robust against common image artifacts and can analyze several image formats. The automatic nature of the script removes human error and allows large numbers of images to be analyzed quickly with high precision. The stripe width precision is generally better than the resolution of the input image.

INTENTIONALLY LEFT BLANK.
1. Introduction

This automatic stripe analysis tool was initially developed to characterize the e-beam patterning of hydrogen silsesquioxane (HSQ) on a silicon on insulator (SOI) substrate, but it is applicable to a wide array of metrology applications. In order to produce HSQ resist patterns that are faithful to their as-drawn feature geometries, we must account for the effective point spread function (PSF) of the electronic beam (e-beam). The PSF is a function of the e-beam backscatter from the substrate and other proximity effects associated with resist development. The correction of the PSF is called proximity effect correction (PEC). The first step in measuring the PSF is to analyze the linewidths of several line and space patterns written at different doses in a dose matrix (figure 1). Often, these types of dose matrices consist of a large number of test features (~100) and, to correctly resolve the PSF, the linewidths of the patterned features must be resolved to an accuracy of a few nanometers, despite the ~10-nm resolution of the scanning electron microscopy (SEM) images. This tool provides precision far beyond traditional human picked feature width metrology.
The algorithm is split into several steps including image calibration, automatic rotation, edge finding, and stripe analysis. The script was packaged with a graphical user interface (GUI) for ease of use. All examples are of SEM images; however, the script is applicable to optical microscope and macroscopic images. The program was written in Mathworks’ Matlab scripting environment.

2. **Methods, Assumptions, and Procedures**

2.1 **Image Calibration**

In order to produce measurements applicable to the real world, the pixels per meter must be calibrated. This calibration only needs to be preformed once for every magnification. The GUI allows the user to draw a line across a known feature size and then enter its physical size in
meters to establish a calibration (figure 2). As the line end placement accuracy is limited by the resolution of the image, longer lines yield more precise calibrations.

**Figure 2.** Calibration line example.

### 2.2 Automatic Rotation

When analyzing an image, the first task is to choose a region of interest (ROI) to analyze, as shown in figure 3a. Older revisions of this algorithm allowed the user to select multiple stripes. However, those older revisions analyzed the stripes with a more primitive method and were susceptible to image compression artifacts and only worked on distinctly bright stripes. The latest revision uses an edge finding method and can analyze single stripes that are bright, dark, or of equal intensity (as long as their edges are distinct). The example starting image shown in figure 3a shows a stripe being selected that is approximately 3° off from vertical.
Figure 3. (a) ROI selection, (b) binary edge image, (c) Radon transform, and (d) standard deviation of a Radon transform.

After selecting the ROI, the remaining tasks are done automatically. After the ROI is defined, the next task is to preliminarily find edges. Several methods exist, though I found the most reliable was the Prewitt (I) method. The Prewitt edge finding method convolves the original intensity image with two 3x3 pixel filters, one that approximates the vertical gradient and one that approximates the horizontal gradient. The two resulting gradient maps are added in quadrature to approximate the gradient magnitude. This method is performed as a function in Matlab. The resulting image is actually a thresholded version (binary valued image) of the gradient magnitude.
image, where all gradient values above a threshold are considered edges and the remaining area is not. The result of performing the Prewitt edge detection on the ROI of figure 3a is shown in figure 3b.

In order to determine the stripe width, the rotation angle must be found. Once found, the original edges may be analyzed with the rotation angle or the original image may be rotated and the edges found again. It is easier and faster to perform the later. To find the rotation angle, I chose to perform a Radon transform (2) of the binary edge image. The Radon transform integrates the image pixel values along a given direction and then repeats this process for several different directions. It is typically performed over a full 180° set of rotation angles, but I have chosen to implement it over a high resolution subset extending from −5° to +5° in 0.1° increments. The result of performing the Radon transform of figure 3b is shown in figure 3c. It is less computationally intensive to perform the Radon transform on the binary edge image than it is to perform several trial rotations of the original image, and it yields a more accurate result than performing several trial rotations of the preliminary binary edge image. I have assumed, as is often the case, that the stripes will be either nearly vertical or nearly horizontal in the starting image. The ±5° Radon transform subset illustrated above is only meaningful for nearly vertical stripes. The above discussion is written to elucidate the concept; the script actually performs a pre-alignment check step that determines whether the binary edge image has nearly vertical or nearly horizontal edges and performs the Radon transform over either −5° to +5° or 85° to 95° appropriately. This pre-alignment check is done by averaging the binary edge image in the horizontal and vertical directions, and then measuring the standard deviation of both results. When the edges are nearly vertical, the vertical average yields a higher standard deviation and vice versa. This pre-alignment check is faster than performing two high-resolution Radon transforms.

The standard deviation of the Radon transform generates a plot with a peak at the ideal orientation angle. The standard deviation plot of the Radon transform of figure 3c is shown in figure 3d. This rotation angle is used to perform a bilinear rotation transform of the ROI image, resulting in a new ROI image with stripes that are vertical to within <0.05°. This rotated image is then automatically cropped to remove any border pixels resulting from the image rotation. A rotated and cropped ROI image is shown within the GUI of figure 4. After rotation, the same Prewitt filter is run on the rotated image, as shown in figure 5.
Figure 4. GUI showing analyzed image output.
2.3 Stripe Analysis

Note that (as is common in SEM images) the feature edges of figure 3a are highlighted due to electron charging and are detected as multiple edges. The first task in analyzing the stripes is to categorize and label each edge. This is done by a Matlab function that looks for connectedness among the edge lines. The resulting labeled edges are shown as colored lines in figure 5.

There are three cases of errors that occasionally occur and must be addressed. The first case is of edges that are not associated with the stripe geometry. These types of errors typically stem from image compression artifacts or particles in the field areas of the image. To combat this error, lines that extend <10% of the ROI image height are removed. The assumption here is that all artifacts or particles do not extend across a significant portion of the ROI image height.

The second error case is that of non-contiguous edges. To combat this, a search is performed across every edge line whereby any set of edges that are within the horizontal standard deviation of each other are relabeled as being part of the same edge.

The third error case arises when adjacent edge lines are connected resulting in labeled edges that contain multiple edge segments. The solution to this error is combined with the overall goal of the stripe analysis, which is to choose only the outermost edge pixels. This process results in two labeled edges that represent the exterior border of the stripe, whether it is a bright stripe, dark stripe, or of equal intensity (assuming their edges are distinct). The average distance between these exterior edges is the stripe width.

Often it is important to analyze the edges themselves to gauge edge roughness. The script averages the root mean square (RMS) edge roughness of each exterior line and outputs the result. In certain situations, the peak-to-peak edge roughness is more meaningful than the RMS edge roughness, so the script also outputs this value.
2.4 GUI Design

The script was wrapped with a GUI for ease of use by the end user, as shown in figure 4. This was done so that anyone in the organization that had proper Matlab licensing could use this utility without having to understand how it works. The GUI was designed to be very intuitive and efficient. The analysis process flow is split into three simple user tasks.

The first step is to load a starting image using a file browser similar to Windows. Once selected, the second step is either to enter a pixels-per-meter calibration value or click the calibrate scale button. The calibrate scale button invokes the calibration window shown in figure 2. The third step is to automatically perform the image rotation and stripe analysis. The stripe width and edge roughness values are output in the results area at the bottom of the GUI.

For ease of use, the calibration value remains until it is changed; therefore, multiple images may be loaded and analyzed within a single invocation of the GUI. Also, all relevant information about the analyzed image is logged in an output stream of text, including filepath, filename, pixels per meter, stripe width, RMS edge roughness, and peak-to-peak edge roughness.

3. Conclusions

The process of automatically analyzing striped features in images for metrology was discussed. The algorithm was implemented in Mathworks’ Matlab scripting environment and wrapped with a GUI for ease of use by end users. The algorithm has been tested by several users and found to be robust to common image artifacts. The GUI outputs the average stripe width and edge roughness values. Note that the precision of the average stripe width is defined as the RMS edge roughness and that this precision is below the image resolution when ROI stripe selections are more than a few pixels in height. The longer the SOI, the more accurate the average stripe width result will be. By removing human error from the analysis, large numbers of images can be quickly analyzed with high precision.

The script itself is included in the appendix for interested readers. This script includes the GUI function calls; however, the associated GUI figure window is not text based and cannot be included with this report. Please contact me directly if you wish to investigate the GUI further or if you would like to use the application.

Appendix. Source Code

The following is the Matlab script source code including the GUI portions.

function varargout = analyzeSEMstripesGUIv32(varargin)
% This script attempts to fix the inability of analyzeSEMstripes22.m to
% properly analyze SOIj28 A1.tif. This script now finds the
% stripewidth
% of any selection, whether they be bright or dark stripes depending
% on how
% the ROI was selected. This version allows only one stripe to be
% selected. Image filetypes supported:
% (*.bmp,*.gif,*.jpg,*.pbm,*.pcx,*.pgm,*.png,*.ppm,*.ras,*.tif)
% v3.2 Changed file menu load image shortcut to ctrl-f instead of
% ctrl-1.
% Added a GUI button to load images. Fixed a bug when you cancel the
% load
% image file browser. Allowed the GUI to be rescalable. And added a
% max
% edge span output to aid in roughness analysis.

% --- Executes during object deletion, before destroying properties.
function pushbutton4_DeleteFcn(hObject, eventdata, handles)
% hObject handle to pushbutton4 (see GCBO)
% eventdata reserved - to be defined in a future version of MATLAB
% handles structure with handles and user data (see GUIDATA)

% --- If Enable == 'on', executes on mouse press in 5 pixel border.
% --- Otherwise, executes on mouse press in 5 pixel border or over pushbutton6.
function pushbutton6_ButtonDownFcn(hObject, eventdata, handles)
% hObject handle to pushbutton6 (see GCBO)
% eventdata reserved - to be defined in a future version of MATLAB
% handles structure with handles and user data (see GUIDATA)

% --- Executes during object creation, after setting all properties.
function pushbutton6_CreateFcn(hObject, eventdata, handles)
% hObject handle to pushbutton6 (see GCBO)
% eventdata reserved - to be defined in a future version of MATLAB
% handles empty - handles not created until after all CreateFcns called
